by the Committee for Meteorites (B.I. Vronskiy - 1959-1960 and A.V. Zolotov - 1959-1961). The present paper reviews briefly the results obtained by the CIE and compares them with those obtained by other workers. A chart is reproduced showing the marsh and woodland distribution and magnetometric profiles in the neighbourhood of the epicentre. It was found that the marshes were apparently natural formations, unaffected by the fall but there were some arboreal features indicating the effect of the fall on trees. A study was made in 1960 of the felling of trees as a result of the fall of the meteorite. Analysis of these data showed that the height at which the meteorite exploded was 10.5 ± 3.5 km. Magnetometric searches revealed the absence of major magnetic losses. Other studies revealed a region with enhanced concentration of Ni, Co and Mo in the soil and Ce, La, Y and Yb in the wood ash. This region was 2-6 km N.W. of the epicentre. A further series of measurements was concerned with the residual radioactivity in the region. Previous conclusions regarding the increase in radioactivity near the epicentre, as compared with greater distances, were not confirmed. It is suggested that the

TITLE: Some results of studies of the problem of the  
Tungusska meteorite

PERIODICAL: Geologiya i geofizika, no. 1, 1963, 111 - 123

TEXT: A Composite Independent Expedition (CIE) was organized in 1959 and a number of scientific workers and engineers from institutions of Tomsk, Moscow, Novosibirsk and other towns participated in it. The aim of this expedition was to carry out a composite study of the region of the fall of the meteorite. Field work was carried out in 1960 together with a Moscow expedition directed by V.A. Koshelev. There was an expedition in the summer of 1961 organized by the Komitet po meteoritam AN SSSR (Committee for Meteorites of the AS USSR) under the direction of K.P. Florenskiy. The CIE was a part of the latter expedition. Parallel field work was carried out during 1959-1961

ABSTRACT: The program of the Tomsk Medical Institute (Betatron Laboratory) expedition begun in 1959 and its purposes are discussed. The background and a critical review of facts as known in 1959 are given. It includes the summary of witness accounts, geophysical data, night illumination studies and discussion of the immediate area of meteor impact. The objective set forth by the expedition was to compile all facts relating to the Tungus event. The program included study of regions not affected by the meteorite in order to develop control samples. A survey of meteorological and astronomical records of stations in all parts of the world was also made. The second part of the article includes a resume of data obtained by the expedition and a list of new, and confirmation of old facts is given. The conclusion of the work of the ex-

Oxychlorides of rare earths of lowest ...

nitric acid. It oxidizes easily at 300-400°C forming mixtures of oxides of rare earths at higher temperatures. In another series of experiments, the reaction of oxygen with chlorides of rare earths in an open bath at 580 - 600°C was studied. A graphite vessel was used as electrolyzer and anode, and molybdenum rods were used as cathodes. The electrolyte was a mixture of chlorides of rare earths and potassium chloride (50%  $\text{MeCl}_3$  and  $\text{KCl}$ ). The amount of lowest oxychlorides formed in all experiments depended on the amount of products in the bath obtained by decomposition of salts under the action of oxygen and moisture. Finally, the misch metal in the potassium chloride melt was anodically dissolved at 650°C in an open and a closed bath. The authors always found oxychlorides of lowest valencies with a ratio equal to that of initial substances. Summary: In the case of interaction between oxygen, chloride melts of rare earths, and misch metal mixtures of low-valency oxychlorides of rare earths were obtained. The summational reaction can be written down:  
$$4\text{MeCl}_3 + 3\text{O}_2 + 8\text{Me} \rightarrow 6\text{Me}_2\text{OCl}_2$$
 The formation of oxychlorides on the cathode may be explained by the formation of  $\text{Me}_2\text{OCl}_4$  soluble in the melt by

TITLE: Oxychlorides of rare earths of lowest valencies

SOURCE: Elektrokhimicheskie rasplavlennye soley i tverdykh elektrolytov,  
no. 1, 1960, 55-60

TEXT: The interaction of oxygen and rare earth metals with chloride melts of rare earths was studied. In the first series of experiments, the authors used a misch metal (% by weight: 22.5 La, 53.0 Ce, 4.53 Pr, and 16.3 Nd) obtained by electrolysis, and a chloride mixture (% by weight: 26 La, 53.9 Ce, 4.85 Pr, 11.42 Nd) obtained by chlorination of oxides of rare earths with gaseous chlorine in the presence of carbon. The result was a deposit of oxychlorides of lowest valency:  $\text{Me}_2\text{OCl}_2$ , where Me stands

for La, Ce, Pr, and Nd. This mixture is slowly hydrolyzed in water to the hydrates of highest valency. When boiling, decomposition proceeds rather quickly. During heating, the product readily reacts with acids, particularly

TEXT: The authors studied the reaction of a mixture of chlorides of rare earths with mishmetal in the presence of  $O_2$ . They separated a mixture of oxychlorides of lowest valency,  $M_2OCl_2$  ( $M = La, Ce, Pr, Nd$ ). They studied some properties of these compounds. In the electrolysis of chloride baths where the possibility of a contact of  $O_2$  of air and moisture with the melt was not excluded, it was shown that the oxidation of the salts apparently yielded oxy cations  $M_2OCl_2^{2+}$  which were discharged on the cathode and, thus, were transformed to the oxychlorides of lowest valency,  $M_2OCl_2$ . The anodic

("Tr. In-ta elektrokhimii. Ural'skiy fil. AN SSSR", 1960, no. 1, 55-60)

TEXT: An investigation was made of the interaction of mixtures of rare earth chlorides and "mishmetall" in the presence of  $O_2$ . A mixture of low valence oxychlorides,  $Me_2OCl_2$ , was singled out where the metals were La, Ce, Pr, Nd. Some of their properties were investigated. It is shown that in electrolysis of chloride bathes, where the possibility of a contact of atmospheric  $O_2$  and moisture with the melt was not excluded,  $Me_2OCl_2^{2+}$  oxyocations are apparently formed as a result of the oxidation of salts. The discharge of these oxyocations on the cathode causes the formation of oxychlorides of lower valence, the  $Me_2OCl_2$ . The anodic dissolving of mishmetal was investigated. During the anodic dissolution in the melts 2-valent chlorides of rare earths are formed, whose interaction with  $O_2$  causes also the formation of oxychlorides of the same composition. T. K.

Title : On Reactivity and Thermal Transformations of Sphalerite

Orig Pub : Izv. AN SSSR, Otd. tekhn. n., 1956, No 6, 168-171

Abstract : Investigated was the dependence of heating rate of a specimen of sphalerite on the temperature at a constant flow of heat. Chemical composition of specimen (in %): Zn 65.15, S 32.25, Pb 0.42, Fe 0.78. Correlation between rate of heating (degree/minute and temperature is represented by a graph which is of the nature of sudden changes with a gradual subsidence on increase in temperature to 650°. The curve shows two sharply manifested maxima (at 650 and 950°) and two minima (at 850 and 1020°), after which the curve extends upward. Anomalous progression course of the graph is due to the occurrence of a number of thermal transformations associated with changes in state of crystal lattice. A correlation has been ascertained between intervals of thermal transformations of ZnS and temperature of critical points of the forming elements.

TITLE: Separating rare-earth metals by fused salt electrolysis

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 8, 1962, 27, abstract 8G180 ("Tr. In-ta elektrokhimii, Ural'skiy fil. AN SSSR", 1961, no. 2, 131 - 134)

TEXT: Separation of rare-earth metals was investigated in fused bath electrolysis containing a mixture of rare-earth chlorides. It was found that at all the  $D_c$  (0.25 - 1.5 amp/cm<sup>2</sup>) and temperatures (850 - 870; 560 - 700°C) investigated, alloys are obtained which are considerably impoverished of La (3 - 5 weight %) and enriched with Ce (up to 80%). The total Pr and Nd amount remains practically constant. The nature of cathodic deposits varies noticeably with temperature. Their salt content varies from 75 to 80% at 560°C and from 30 to 40% at 700°C. There are 11 references.

the best hyposulphite concentration 10 to 20% (Fig 2) and duration 12 to 15 minutes (Fig 3). On the basis of these satisfactory results production trials on a mechanically-stirred vessel of 4.2 m<sup>3</sup> capacity were organized. In one series iron-free solutions were used, in the other the solutions contained iron. The results (table) were substantially the same in both series but the duration of the subsequent operation of cobalt precipitation by chlorine took 50% longer with the iron-free solutions. The consumption of hyposulphite could be reduced to 4.5 kg/kg copper by increasing the time interval between successive additions to 30 minutes and the cobalt content in the cake was low enough (0.1% max) to make further treatment unnecessary. The yield of copper cake was twice as low as with soda ash. The authors conclude that the possibility of copper

TITLE: Elimination of Copper from the Cobalt-Oxide Production  
Cycle (Vyyvod medi iz tsikla pri prizvodstve okisi  
kobal'ta)

PERIODICAL: Tsvetnyye Metally, 1959, Nr 2, pp 49-52 (USSR)

ABSTRACT: The existing method at the Ufaleyskiy Nikellevyy Zavod  
(Ufaley Nickel Works) for removal of copper from cobalt  
solutions is to precipitate with soda ash. This gives  
a copper cake with 0.3 to 0.5% cobalt which has to be  
reprocessed, leading to deleterious accumulation of  
copper in the first stage of cobalt-oxide production.  
The work described had the object of exploring the  
possibilities of using sodium hyposulphite for the  
precipitation, giving a copper cake which could be  
eliminated from the production cycle. Laboratory  
experiments showed (Fig 1) that 300% (or 7.5 kg per kg  
copper) of the theoretical amount of hyposulphite was  
necessary to precipitate all the copper independently  
of acidity (0.04 to 0.05% Co in the precipitate), that  
the best temperature for precipitation was 80 to 90°C

Spectrophotometry of the Biuret Complexes as Method of Investigating the Polypeptides and Proteins. XIX. On Some Reactions of the Exchange Cleavage of Copper Biuret Complexes

maximum absorption is. The greater the difference in this wave length of the maximum absorption the higher is the velocity and the completeness with which the displacement of the one component by the other takes place. The stability of these complexes in the above mentioned cleavage reactions directly depends on the composition of the coordination bonds. The best stability is in that complex which contains 4 nitrogen containing groups in the inner coordination sphere, which, however, are not equivalent in this sense. The coordination bonds obtain their best stability from the peptide group. In their substitution in the coordination sphere of the complex by other groups a displacement of the maximum to the side of the long waves takes place which is determined by a quantity characteristic of each group. The glycyl tetrapeptide quantitatively displaces the tripeptides and proteins (among them the insulin) from the biuret complexes. The displacement reaction can be used as a method of determining the copper numbers. There are 10 figures, 3 tables, and 8 references, 3 of which are Soviet.

PERIODICAL: Zhurnal obshchey khimii, 1958, Vol 28, Nr 11, pp 3133-3143 (USSR)

ABSTRACT: The direct dependence of the complex properties on the composition of the coordination bonds is also proved in this paper, where the authors investigated the relative stability of the copper biuret complexes in some reactions of the exchange cleavage. These complexes can in this cleavage be quantitatively decomposed by the components forming the biuret complex with maximum absorption on the shortest wave length of the visible spectrum. The position of the maximum absorption can serve as a characteristic feature of the comparative stability of the copper biuret complexes in these reactions: The complex is the more stable the shorter the wave length of the

Spectrophotometry of biuret complexes as a method of study of proteins and peptides. XVIII. Biuret reaction of polypeptides with interrupted chain. M. I. Plekhan (Inst. Moscow Med. Inst.), Zhur. Oshchel. Akad. Nauk SSSR (1955); cf. C.A. 49, 4801f; 49, 3776.—The biuret complex of  $(\text{CH}_2\text{CH}_2\text{CH}_2\text{NHCONHCH}_2\text{CONHCH}_2\text{C}_6\text{H}_5)$ , has an absorption max. 560 m $\mu$  and contains 2 atoms of Cu per mole. The biuret complex of the analogous hexamethylenebis(ureidoacetylidiglycylglycine) has absorption max. 565 m $\mu$  and also contains 2 atoms Cu per mole. The formation of the biuret complex of hexamethylenebis(carbonyldiglycylglycine) occurs only to the extent of 8% and the complex has absorption max. 530 m $\mu$ . Thus, in substances in which the peptide chain is interrupted by another unit, each peptide fragment forms an individual biuret complex, the character of which depends on the no. of peptide units in the fragment and the nature of the non-peptide link attached to it. Possible configurations of the biuret complexes of these substances are shown.

Title : Structure of gramicidin C

Periodical : Zhur. ob. khim. 24/9, 1694-1695, Sep 1954

Abstract : Critical review is presented of the book by P. G. Ioannisiani, N. I. Gavrilova and M. I. Plekhan, entitled, "Structure of Gramicidin C". The statement that the structure of gramicidin, characterized by the presence of a diketopiperazine heterocycle and free final carboxyl group is discussed. Two USSR references (1949 and 1954).

Title : The structure of gramicidin C. Part 1.- Reduction of gramicidin C.

Periodical : Zhur. ob. khim. 24/2, 364-369, Feb 1954

Abstract : The existence in gramicidine C of two diketopiperazine and tripeptide fragments, the first one of which contains proline, was established experimentally. The peptides found in the products of incomplete gramicidin C hydrolysis are listed. The structural formula for the gramicidin C monomer is presented. Various characteristics of gramicidin C are described. Twelve references: 8-USSR; and 1-French; 3-USA (1939-1953). Tables.

Organic Chemistry

The formation of cyclic peptides is discussed as a method of determining the absolute configuration of amino acids. Previous work has shown that the formation of cyclic peptides is a general method for determining the absolute configuration of amino acids (see, for example, J. C. G. Lepage, *J. Am. Chem. Soc.*, 75, 1032 (1953); cf. G. A. Jeffrey, *J. Am. Chem. Soc.*, 75, 1032 (1953)). The formation of other compounds, e.g., optically active peptides, will probably not lead to racemization, which suggests that the peptide links are enolized in this reaction. The direct peptide formation aids the preservation of optical activity of peptides and protein under prolonged storage conditions. Optical activity of the peptides does not affect the character of their absorption spectrum, as bluet components in the active form of alanine were obtained by the action of penicillin on the racemic (benzyloxycarbonyl) derivative in citrate buffer. (*Benzylxycarbonyl*)-L-alaninate, m. 159-60°, obtained as described above and hydrolyzed by heating 6 hr. with concd. HCl, yielded 85.6% L-alanine, which gave the (*benzyloxycarbonyl*) derivative, m. 83-4° (from HO). (*I*-*D*)-*D*-alanine, The peptides were obtained by the usual methods; however, the acyl chlorides are poorly soluble in  $\text{CH}_2\text{Cl}_2$  and  $\text{CHCl}_3$ ; hence, they must be kept cold. To remove the  $\text{Hg}^{2+}$  from the (*benzyloxycarbonyl*) peptides the  $\text{MeOH}$  solution of the product is treated with 10%  $\text{Na}_2\text{CO}_3$  until alk. (about 10 min. *in situ*) and exdt. with  $\text{MeOH}$ , leaving behind  $\text{Na}_2\text{CO}_3$ . Reduction of the (*benzyloxycarbonyl*) peptides must be done in a medium in the presence of a little  $\text{NaOH}$ . Thus were obtained the (*benzyloxycarbonyl*) ester of *racemic* *d*-alaninate, oil, *D*-alanine, m. 120°, and *L*-*D*-alanine, oil. The tripeptides were also obtained similarly: *racemic* *D,L,D,L-alanide*, decomp. 210°; *L-alanyl-L-alanyl-L-alanine*, decomp. 230°; *D-alanyl-D-alanyl-D-alanine*, decomp. 230°. (Rising, et al., *J. Am. Chem. Soc.*, 75, 1110). G. M. Kunkel

Reaction of glyoxal with amino acids. M. I. Plekhan and S. R. Mardashev [Sci. Research Lab., Ministry of Health, Moscow], *Sbornik Statei Obrashchel Khim.*, 2, 1645-53 (1953). Glyoxal (I) reacts with mono-amino acids through but 1 CHO group and 1 NH<sub>2</sub> group. The reaction occurs in 2 steps through formation of a colorless compound of type HO<sub>2</sub>CCHRN:CHCHO (II), which then passes into the colored cyclic product HO<sub>2</sub>CCHRN:CHCH(OH) (III), which is stable. The colorless intermediate is destroyed by NH<sub>2</sub>OH, *p*-phenylenediamine, semicarbazide, with formation of the corresponding I deriv. and liberation of the amino acid. Reaction of 38% aq. I with amino acids proceed best in aq. medium with excess I at about 0°. To 2 g. H<sub>2</sub>NCH<sub>2</sub>CO<sub>2</sub>H in 2 ml. H<sub>2</sub>O was added with ice cooling 3 ml. 38% aq. I (neutralized to pH 8 with CaCO<sub>3</sub> or Na<sub>2</sub>CO<sub>3</sub>) and after 45 min. the soln. was treated with 60-70 ml. abs. MeOH and 30-40 ml. abs. Et<sub>2</sub>O, yielding 70% II; this was taken up in H<sub>2</sub>O, treated with (CO<sub>2</sub>H)<sub>2</sub> to remove the admixed Ca salt of an org. acid contaminant present in concn. I, filtered and again ptd. with Et<sub>2</sub>O-MeOH. II (*R* = H), thus obtained is washed with abs. Me<sub>2</sub>CO and Et<sub>2</sub>O and dried *in vacuo*. To 0.5 g. glycine Cu salt in 6 ml. H<sub>2</sub>O was added with cooling 4 ml. 38% I (neutralized as above), cooled 1 hr. longer, then kept 3.0 hrs. at room temp., then treated with MeOH-Et<sub>2</sub>O yielding light blue ppt. of the Cu deriv., C<sub>6</sub>H<sub>9</sub>O<sub>4</sub>NCu<sub>2</sub>·3H<sub>2</sub>O. Heating the aq. soln. of II (*R* = H) on a steam bath until CHO test is neg. gave after addn. of MeOH-Et<sub>2</sub>O a ppt. of III (*R* = H), isolated as a monohydrate. II (*R* = Me) ptd. similarly from alanine, isolated as hemihydrate. Heating aq. solns. of II in acid or basic conditions results in formation of III, which was followed spectrophotometrically; the curves of reaction progress are shown. Electrolytic reduction of III resulted in no reduction at the cathode (no color loss) while at the anode the product was oxidized to H<sub>2</sub>NCH<sub>2</sub>CO<sub>2</sub>H and HCOCO<sub>2</sub>H.

*Spectrophotometry of biuret complexes as a method of study of proteins. XII. Spectrophotometric study of formation of copper biuret complex in the presence of a mixture of two peptides with chains of different lengths.*  
 M. I. Plekhan (Moscow State Univ.), *Zhur. Obshchey Khim.* (J. Gen. Chem.) 21, 574-9 (1951); cf. *C.A.* 45, 5198g.  
 Addn. of 0.25 M Cu(OAc)<sub>2</sub> to a mixt. of 2 ml. 0.05 M glycine tripeptide and 2 ml. 0.05 M glycine dipeptide in 3 ml. 2 N NaOH and 0.5 ml. H<sub>2</sub>O in graduated portions (total 1.5 ml.), filtration of pptd. Cu oxide, and examin. of the solns. after the addns. of the Cu salt spectrophotometrically showed that the tripeptide reacts first, giving a violet soln., but the curve has a max. at 550 m $\mu$ , instead of 578 m $\mu$  normal for the individual tripeptide; apparently the dipeptide also enters the complex to some extent; as the addn. of Cu continues the max. of the curve shifts to 670 m $\mu$ , and finally to 610 m $\mu$ , giving a very nrm. curve, which is at every point much higher than called for by simple arithmetic sum of the absorptions of possible components. Similar examin. of mixed di- and tetrapeptides of glycine gave at first the red color typical of the tetrapeptide complex, followed by participation of the dipeptide, the abs. max. shifts but little from 620 m $\mu$  to 630 m $\mu$ , but an indication of an inflection at 610-730 m $\mu$  is evidently the dipeptide contribution, showing up near the end of the reaction; again the summary curve is not an additive one. A similar mixt. of the tri- and tetrapeptides gives the initial reaction of the tetrapeptide (max. 520 m $\mu$ ), followed by greater participation of tripeptide with the shift of abs. max. to 530 m $\mu$  with appearance of a faint max. about 660-730 m $\mu$ . The final curve here is very nearly additive, indicating that the components act independently in this instance. XIII. Analysis of the spectrophotometric curves of biuret copper complexes of serum albumin, casein and gelatin. *Ibid.* 570-84.—Numerous spectral curves of mixts. of tri- and tetrapeptides of glycine, serum albumin, gelatin, and casein

IIA

in the form of their Cu complexes (prepd. by treatment with Cu(OAc)<sub>2</sub> in dil. NaOH) are presented and summarized. Regardless of the ratio used, mixts. of tri- and tetrapeptides give curves that are additive in respect to the components, indicating formation of a simple mixt. of the individual biuret complexes. The Cu biuret complexes of the proteins, however, appear to be mixts. of the biuret complexes of tri- and tetrapeptide types in ratio of 90-95% to 10-5%, resp. The abs. max. for the serum albumin complex is at 555 m $\mu$ ; that of gelatin is at 505 m $\mu$ , and that of casein at 580 m $\mu$ . Hence, proteins definitely contain some simple tripeptides

Spectrophotometry of bluet complexes as a method of protein study. X. Spectrophotometric study of copper bluet complexes of hepta and octapeptides. M. I. Plekhan (Moscow State Univ.), Zhur. Obshchey Khim. (J. Gen. Chem.) 21, 812-18 (1951); cf. C.A. 43, 6240; 43, 3434g.—The polypeptides were prep'd. according to Fischer's method (C.A. 1, 61); the replacement of Br by NH<sub>2</sub> in the final step was done by means of concd. aq. NH<sub>3</sub> soln. for 8 days at 25°. The spectrophotometric curves for: glycylglycine, diglycylglycine, analogous tetra-, hexa-, and pentapeptides, heptapeptide (leucylpentaglycylglycine), and octapeptide (leucylhexaglycylglycine) in the form of their Cu complexes are reproduced. The dipeptide gives a max. at 670 m $\mu$ , tripeptide at 675 m $\mu$ , tetrapeptide at 620 m $\mu$ , pentapeptide at 605 m $\mu$ , hexapeptide at about the same value, heptapeptide at 520 m $\mu$ , and octapeptide at 530 m $\mu$ . The last 2 have much higher extinction values than the lower derivs. As chain length grows the spectrum departs more and more from that of a protein (casein). The Cu complexes of hepta- and octapeptides have 2 Cu per mole, each bound by normal valences (2) to the enol-O atoms of adjoining amino-

acid units, and by either 3 coordinate valences to the 3 N atoms spatially distributed at reasonable distances from the Cu atoms by coiling of the peptide chain, or by 4 such valences. The octapeptide deriv. appears to have 2 Cu atoms with 4-coordinate link systems, while the heptapeptide has 1 Cu atom of each type. XI. Spectrophotometric study of formation of copper bluet complex in a mixture of di-, tri-, and tetrapeptides. Ibid. 316-21.—The peptides (all glycine types) when mixed and treated with Cu(OAc)<sub>2</sub> 1st display the reaction of the tetrapeptide (red); then the tripeptide and last the dipeptide reaction. The summary photometric curve has a max. at 550 m $\mu$  and a 2nd lesser max. at 670 m $\mu$ . The curve's shape differs much from that of a typical protein. Furthermore, photometry of such a mixed soln. of Cu complexes does not obey arithmetic additivity of extinction of the individual components. The red complex forms so much more readily and rapidly than the violet or blue, that the tetrapeptide, in cases of deficiency of Cu in soln., actually displaces tri- and dipeptides from their already formed complexes. The actual extinction of the mixt. is higher than calcd. (or arithmetic sum) from 500 to 730 m $\mu$ , and lower from 480 to 380 m $\mu$ . G. M. Kosolapoff

**spectrophotometry of biuret complexes as a method of study of proteins. IX. Spectrophotometric studies of biuret complexes of polypeptides and protein with nickel and cobalt.** M. I. Plekhan and A. M. Kan (Moscow State Univ.), *Zhur. Obshch. Khim.* (J. Gen. Chem.) 20, 2105 (1950); cf. C.A. 43, 6240f. Biuret complexes of peptides (glycylglycine, chloroacetylglycylglycine, diglycylglycine, chloroacetyldiglycylglycine, triglycylglycine, tetraglycylglycine) with Ni form slower than with Cu; casein behaves similarly. Dipeptides give blue complexes, tripeptides orange, tetra- and penta-peptides give yellow, and casein gives orange complexes. The spectrum curves do not show maxima, except for dipeptide curve (max. about 600 m $\mu$ ), but all show a min. at 640-660 m $\mu$ . The curves are reproduced. Ni complexes were formed from  $Ni(NO_3)_2$  in dil NaOH soln. with the amino acid deriv.; after filtration from  $Ni(OH)_2$ , the solns. were examd. spectrographically. Co complexes were prep'd. with  $Co(NO_3)_2$  as above. Casein Ni complex resembles those of tripeptides, rather than of longer chain polypeptides both in color and the shape of the absorption curve. The dipeptide curve differs from those of other peptides or casein possibly because the protein does not contain true dinucleotide groups. Co complexes of peptides and casein are red-brown and differ only in the degree of absorption. Ni complex of biuret is yellow and has an absorption min. at 600 m $\mu$ , while that of Co is red-brown with max. absorption at 480 m $\mu$ . The intensity of absorption of Co complex of dipeptide is so much greater than that of Co complexes of free amino acids that it may be used for qual detection of dipeptides in mixts. with amino acids.

The optimum conditions of wool scouring. S. S. Rakha and M. I. Plekhan. *Sherstyane Jela* 1935, No. 3, 19-21; Nov. 4-5, 17-21. -The fats remaining on the wool after treatment in the successive scouring tanks have lower acetyl values and higher I values; the unsaponifiable matter, the acid value and the sapon. value are unchanged. The supposition that the high-melting fats remain in the wool at the end of the scouring is disproved. Removal of fat from wool is best accomplished with soap-soda solns. producing stable emulsions. The soap forms absorption films on the surface of the fat drops and creates in the soln. a concn. corresponding at least to the satn. limit of the surface layer. Soda forms soaps with the free acids of the wool, maintaining the soap introduced into the tank at optimum dispersion at a definite pH value of the medium. The optimum concns. of the scouring liquor are soap equiv. to 0.8-0.9 g., fat acids and soda 3-5 g. per l. R. V. Shvartzberg

built in Poland. Several experiments requiring low power have been shifted to MARYLA, thus making it possible to run EWA round the clock on full power (in 1962 utilization was 88 hours per week). EWA has been used for training reactor operators and in work leading to many MSc and PhD degrees. There has been collaboration with foreign reactor centers and with the United Institute for Nuclear Research (Budapest, USSR). Two charts showing utilization of EWA are presented. Orig. art. has: 4 figures.

other equipment (all Polish-made) make it possible to conduct research on crystal and magnetic neutron structure analysis, neutron-phonon, and neutron-magnon interactions, microdynamics of molecules, fast neutron induced damage in semiconductors, neutron resonance scattering, ( $n, \gamma$ ) reactions (including short-lived isotopes), tri-partition of U-235, neutron diffusion, and neutron flux and spectra measurements. Irradiation facilities in the reactor make it possible to conduct activation analysis, to study the chemistry of hot atoms, and to produce radio isotopes widely used in Poland in the physical and chemical sciences, the life sciences, and in industry. EWA is also the object of extensive studies, changes, and improvements, such as mechanical and ion-exchange filters for the first cooling circuit, corrosion studies, automatic control of slow reactivity changes, et cetera. Changes are being introduced to meet the actual and constantly varying requirements of users. The power of the reactor is to be increased to 4 Mw in 1964 and plans have been made to reach 10 Mw by 1966. A flexible and inexpensive zero power reactor MARYLA which uses the same fuel elements as the EWA has been put into operation, in the same reactor hall. This reactor and a similar reactor ANNA (also located at Swierk) were designed and

"EWA"

SOURCE: Nauka i Technika, v. 9, no. 7-8, 1964, 511-522

TOPIC TAGS: nuclear reactor, reactor utilization, Poland, EWA

ABSTRACT: The Polish research reactor EWA at Swierk (2Mw, enriched uranium, light water moderated and cooled, with an average thermal neutron flux of  $10^{13}$  neutrons  $\text{mm}^{-2}\text{-sec}$ ), received from the USSR, became critical in 1958. The nine horizontal experimental channels and the thermal column are used for research in the fields of solid state, nuclear, and reactor physics. Three triple-axis neutron crystal spectrometers, a cold neutron unit (beryllium filter and a slow chopper with curved slits), three slow choppers, a fast chopper, special apparatus for in-pile irradiation, a pile oscillator, and

TITLE: A method of producing carrier-free sulfur  $S^{35}$  in the form of  $H_2S^{35}O_4$

PERIODICAL: Referativnyy zhurnal. Khimiya, no. 1, 1962, 329, abstract 1K5 ([Referat.] Inst. badan jadrow. PAN, no. 192/XIII, 1960)

TEXT: Radioactive  $S^{35}$  is produced on a commercial scale in the form of  $H_2SO_4$ . In this case the  $H_2SO_4$  is obtained without carrier by irradiation of a  $KCl$  target with a neutron flux ( $10^{13}$  neutr/cm $^2$ ·sec) for a period of four weeks. The main product is obtained from the reaction  $Cl^{35}(n,p)S^{35}$ . In addition to  $S^{35}$  irradiation produces  $K^{42}$ ,  $P^{32}$ ,  $Cl^{36}$ , and  $Cl^{38}$ ; of these the sulfur and phosphorus immediately oxidize and take the form of ions  $PO_4^{3-}$  and  $SO_4^{2-}$ , whilst the  $K^{42}$  and  $Cl^{38}$ , which have a very short half-life, virtually disappear. After the irradiated target has been

TITLE: New method for producing carrier-free H sub 2 S sup 35 O sub 4 on a production scale

SOURCE: Kernenergie, no. 1, 1964, 38-40

TOPIC TAGS: radioisotope, production, H sub 2 S sup 35 O sub 4, carrier-free, separation, neutron, radiation, reactor, KCl.

ABSTRACT: S<sup>35</sup> is obtained by neutron irradiation of KCl in a reactor. Two chromatographic columns are used to separate S<sup>35</sup> from the irradiated target. The first is charged with Al<sub>2</sub>O<sub>3</sub> and serves to separate sulfur from P<sup>32</sup>, Cl<sup>36</sup>, Cl<sup>38</sup>, K<sup>42</sup>, and the main portion of KCl. The second one is charged with a cation exchanger in H<sup>+</sup> form to separate sulfur from all cationic impurities including K<sup>+</sup>-residues, and assures the presence of sulfur as H<sub>2</sub>SO<sub>4</sub>. The column parameters are selected so that a single application of the two columns suffices. Carrier-free, S<sup>35</sup>-tagged H<sub>2</sub>SO<sub>4</sub> in 10<sup>-2</sup> - 10<sup>-3</sup> n HCl is obtained of purity greater than 99%. The specific activity is 35 mc/ml, and the pH is 2-3. The radicisotope may be used for medical

AUTHORS: Seidl, Rudolf and Plecitý, Václav  
TITLE: Criterion forming circuit for register impulsing  
PERIODICAL: Referativnyy zhurnal, Avtomatika i radioelektronika,  
no. 12, 1962, 20, abstract 12-8-391 (Czech. pat.,  
cl. 21a3, 32/20, no. 98135, Jan. 15, 1961)

TEXT: An automatic exchange circuit is patented, intended for control of register impulsing. It consists of two relay sets, the first of which counts received pulse trains and the other counts pulse trains sent from the register via the appropriate contacts of both sets. Relay contacts of the first set, dependent on the number of received digits, are switched in such a manner that a galvanic connection is established between the input and the contact signifying the number of received digits. Depending on the number of digits sent out, relay contacts of the second set form a galvanic connection between the output and the contacts which record how many of the received digits still remain to be transmitted
